John Tate

Sato-Tate in genus 1

Let E/\mathbb{Q} be an elliptic curve, which we can write in the form

$$y^2 = x^3 + ax + b.$$

Let p be a prime of good reduction for E .

The number of \mathbb{F}_p -points on the reduction of E modulo p is

$$\#\bar{E}(\mathbb{F}_p) = p + 1 - t_p.$$

The trace of Frobenius t_p is an integer in the interval $[-2\sqrt{p}, 2\sqrt{p}]$.

We are interested in the limiting distribution of $x_p = -t_p/\sqrt{p} \in [-2, 2]$, as p varies over primes of good reduction.

Example: $y^2 = x^3 + x + 1$

p	t_p	x_p	p	t_p	x_p	p	t_p	x_p

Sato-Tate distributions in genus 1

1. Typical case (no CM)

Elliptic curves E/\mathbb{Q} w/o CM have the semi-circular trace distribution. (This is also known for E/k , where k is a totally real number field).

[Taylor et al.]

2. Exceptional cases (CM)

Elliptic curves E/k with CM have one of two distinct trace distributions, depending on whether k contains the CM field or not.

[classical]

Sato-Tate groups in genus 1

The *Sato-Tate group* of E is a closed subgroup G of $SU(2) = USp(2)$ derived from the ℓ -adic Galois representation attached to E .

The refined Sato-Tate conjecture implies that the normalized trace distribution of E converges to the trace distribution of G under the Haar measure (the unique translation-invariant measure).

G	G/G^0	Example curve	k	$E[a_1^0], E[a_1^2], E[a_1^4] \dots$
$U(1)$	C_1	$y^2 = x^3 + 1$	$\mathbb{Q}(\sqrt{-3})$	$1, 2, 6, 20, 70, 252, \dots$
$N(U(1))$	C_2	$y^2 = x^3 + 1$	\mathbb{Q}	$1, 1, 3, 10, 35, 126, \dots$
$SU(2)$	C_1	$y^2 = x^3 + x + 1$	\mathbb{Q}	$1, 1, 2, 5, 14, 42, \dots$

In genus 1 there are three possible Sato-Tate groups, two of which arise for curves defined over \mathbb{Q} .

The Sato-Tate problem for an abelian variety

Let A be an abelian variety of dimension $g > 0$ over a number field k .

For every prime \mathfrak{p} of good reduction for A , there exists a unique integer polynomial $L_{\mathfrak{p}}(T) = \prod (1 - \alpha_i T)$ of degree $2g$ for which

$$\#A(\mathbb{F}_{q^n}) = \prod_{i=1}^{2g} (1 - \alpha_i^n)$$

holds for all positive integers n , with $q = \|\mathfrak{p}\|$ [Weil].

Each *normalized L-polynomial* $\bar{L}_{\mathfrak{p}}(T) = L_{\mathfrak{p}}(T/\sqrt{q})$ determines a unique conjugacy class in the unitary symplectic group $\mathrm{USp}(2g)$.

The *Sato-Tate problem*, in its simplest form, is to find a measure for which these classes are equidistributed.

Sato-Tate distributions in genus 2

For $g = 2$, the polynomial $\bar{L}_p(T)$ has the form

$$\bar{L}_p(T) = T^4 + a_1 T^3 + a_2 T + a_1 + 1,$$

with $a_1, a_2 \in \mathbb{R}$ satisfying $|a_1| \leq 4$ and $|a_2| \leq 6$.

Given an abelian surface A/k , we would like to understand the distributions of a_1 and a_2 (and also their joint distribution), as p varies over good primes of norm at most N , with $N \rightarrow \infty$.

A wide range of examples can be found at

<http://math.mit.edu/~drew>

The Sato-Tate group ST_A

Let $\rho_\ell: G_k \rightarrow \text{Aut}_{\mathbb{Q}_\ell}(V_\ell(A)) \simeq \text{GSp}_{2g}(\mathbb{Q}_\ell)$ be the ℓ -adic Galois representation arising from the action of G_k on $V_\ell(A) = T_\ell(A) \otimes \mathbb{Q}$.

Let G_k^1 be the kernel of the cyclotomic character $\chi_\ell: G_k \rightarrow \mathbb{Q}_\ell^\times$.

Let $G_\ell^{1,\text{Zar}}$ be the Zariski closure of $\rho_\ell(G_k^1)$ in $\text{GSp}_{2g}(\mathbb{Q}_\ell)$.

Choose an embedding $\iota: \mathbb{Q}_\ell \hookrightarrow \mathbb{C}$ and let $G^1 = G_\ell^{1,\text{Zar}} \otimes_\iota \mathbb{C}$.

Definition [Serre]

$ST_A \subseteq \text{USp}(2g)$ is a maximal compact subgroup of $G^1 \subseteq \text{Sp}_{2g}(\mathbb{C})$. For each prime \mathfrak{p} of good reduction for A , let $s(\mathfrak{p})$ denote the conjugacy class of $\|\mathfrak{p}\|^{-1/2} \rho_\ell(\text{Frob}_\mathfrak{p}) \in G^1$ in ST_A .

Conjecturally, ST_A does not depend on ℓ ; this is known for $g \leq 3$. In any case, the characteristic polynomial of $s(\mathfrak{p})$ is always $\bar{L}_\mathfrak{p}(T)$.

Equidistribution

Let μ_{ST_A} denote the image of the Haar measure on $\text{Conj}(ST_A)$ (which does not depend on the choice of ℓ or the embedding ι).

Conjecture [Refined Sato-Tate]

The conjugacy classes $s(\mathfrak{p})$ are equidistributed with respect to μ_{ST_A} .

In particular, the distribution of $\bar{L}_{\mathfrak{p}}(T)$ matches the distribution of characteristic polynomials of random matrices in ST_A .

We can test this numerically by comparing statistics of the coefficients a_1, \dots, a_g of $\bar{L}_{\mathfrak{p}}(T)$ over $\|\mathfrak{p}\| \leq N$ to the predictions given by μ_{ST_A} .

The Sato-Tate axioms (weight 1)

A subgroup G of $\mathrm{USp}(2g)$ satisfies the *Sato-Tate axioms* if:

- 1 G is closed.
- 2 (Hodge circles) There is a subgroup H that is the image of a homomorphism $\theta: \mathrm{U}(1) \rightarrow G^0$ such that $\theta(u)$ has eigenvalues u and u^{-1} with multiplicity g , and H can be chosen so that its conjugates generate a dense subset of G^0 .
- 3 (Rationality) For each component H of G and each irreducible character χ of $\mathrm{GL}_{2g}(\mathbb{C})$ we have $\mathbb{E}[\chi(\gamma) : \gamma \in H] \in \mathbb{Z}$.

The Sato-Tate axioms (weight 1)

A subgroup G of $\mathrm{USp}(2g)$ satisfies the *Sato-Tate axioms* if:

- 1 G is closed.
- 2 (Hodge circles) There is a subgroup H that is the image of a homomorphism $\theta: \mathrm{U}(1) \rightarrow G^0$ such that $\theta(u)$ has eigenvalues u and u^{-1} with multiplicity g , and H can be chosen so that its conjugates generate a dense subset of G^0 .
- 3 (Rationality) For each component H of G and each irreducible character χ of $\mathrm{GL}_{2g}(\mathbb{C})$ we have $\mathbb{E}[\chi(\gamma) : \gamma \in H] \in \mathbb{Z}$.

For any fixed g , the set of subgroups of $\mathrm{USp}(2g)$ that satisfy the Sato-Tate axioms is **finite** up to conjugacy.

Theorem

For $g \leq 3$, the group ST_A satisfies the Sato-Tate axioms.

Conjecturally, this holds for all g .

Sato-Tate groups in genus 2

Theorem 1 [FKRS 2012]

Up to conjugacy, 55 subgroups of $\mathrm{USp}(4)$ satisfy the Sato-Tate axioms:

$\mathrm{U}(1)$: $C_1, C_2, C_3, C_4, C_6, D_2, D_3, D_4, D_6, T, O,$
 $J(C_1), J(C_2), J(C_3), J(C_4), J(C_6),$
 $J(D_2), J(D_3), J(D_4), J(D_6), J(T), J(O),$
 $C_{2,1}, C_{4,1}, C_{6,1}, D_{2,1}, D_{3,2}, D_{4,1}, D_{4,2}, D_{6,1}, D_{6,2}, O_1$

$\mathrm{SU}(2)$: $E_1, E_2, E_3, E_4, E_6, J(E_1), J(E_2), J(E_3), J(E_4), J(E_6)$

$\mathrm{U}(1) \times \mathrm{U}(1)$: $F, F_a, F_c, F_{a,b}, F_{ab}, F_{ac}, F_{ab,c}, F_{a,b,c}$

$\mathrm{U}(1) \times \mathrm{SU}(2)$: $\mathrm{U}(1) \times \mathrm{SU}(2), N(\mathrm{U}(1) \times \mathrm{SU}(2))$

$\mathrm{SU}(2) \times \mathrm{SU}(2)$: $\mathrm{SU}(2) \times \mathrm{SU}(2), N(\mathrm{SU}(2) \times \mathrm{SU}(2))$

$\mathrm{USp}(4)$: $\mathrm{USp}(4)$

Sato-Tate groups in genus 2

Theorem 1 [FKRS 2012]

Up to conjugacy, 55 subgroups of $\mathrm{USp}(4)$ satisfy the Sato-Tate axioms:

$$\begin{aligned} \mathrm{U}(1): & \quad C_1, C_2, C_3, C_4, C_6, D_2, D_3, D_4, D_6, T, O, \\ & \quad J(C_1), J(C_2), J(C_3), J(C_4), J(C_6), \\ & \quad J(D_2), J(D_3), J(D_4), J(D_6), J(T), J(O), \\ & \quad C_{2,1}, C_{4,1}, C_{6,1}, D_{2,1}, D_{3,2}, D_{4,1}, D_{4,2}, D_{6,1}, D_{6,2}, O_1 \\ \mathrm{SU}(2): & \quad E_1, E_2, E_3, E_4, E_6, J(E_1), J(E_2), J(E_3), J(E_4), J(E_6) \\ \mathrm{U}(1) \times \mathrm{U}(1): & \quad F, F_a, F_c, F_{a,b}, F_{ab}, F_{ac}, F_{ab,c}, F_{a,b,c} \\ \mathrm{U}(1) \times \mathrm{SU}(2): & \quad \mathrm{U}(1) \times \mathrm{SU}(2), N(\mathrm{U}(1) \times \mathrm{SU}(2)) \\ \mathrm{SU}(2) \times \mathrm{SU}(2): & \quad \mathrm{SU}(2) \times \mathrm{SU}(2), N(\mathrm{SU}(2) \times \mathrm{SU}(2)) \\ \mathrm{USp}(4): & \quad \mathrm{USp}(4) \end{aligned}$$

Of these, exactly 52 arise as ST_A for an abelian surface A (34 over \mathbb{Q}).

Sato-Tate groups in genus 2

Theorem 1 [FKRS 2012]

Up to conjugacy, 55 subgroups of $\mathrm{USp}(4)$ satisfy the Sato-Tate axioms:

$$\begin{aligned} \mathrm{U}(1): & \quad C_1, C_2, C_3, C_4, C_6, D_2, D_3, D_4, D_6, T, O, \\ & \quad J(C_1), J(C_2), J(C_3), J(C_4), J(C_6), \\ & \quad J(D_2), J(D_3), J(D_4), J(D_6), J(T), J(O), \\ & \quad C_{2,1}, C_{4,1}, C_{6,1}, D_{2,1}, D_{3,2}, D_{4,1}, D_{4,2}, D_{6,1}, D_{6,2}, O_1 \\ \mathrm{SU}(2): & \quad E_1, E_2, E_3, E_4, E_6, J(E_1), J(E_2), J(E_3), J(E_4), J(E_6) \\ \mathrm{U}(1) \times \mathrm{U}(1): & \quad F, F_a, F_c, F_{a,b}, F_{ab}, F_{ac}, F_{ab,c}, F_{a,b,c} \\ \mathrm{U}(1) \times \mathrm{SU}(2): & \quad \mathrm{U}(1) \times \mathrm{SU}(2), N(\mathrm{U}(1) \times \mathrm{SU}(2)) \\ \mathrm{SU}(2) \times \mathrm{SU}(2): & \quad \mathrm{SU}(2) \times \mathrm{SU}(2), N(\mathrm{SU}(2) \times \mathrm{SU}(2)) \\ \mathrm{USp}(4): & \quad \mathrm{USp}(4) \end{aligned}$$

Of these, exactly 52 arise as ST_A for an abelian surface A (34 over \mathbb{Q}).

Note that our theorem says nothing about equidistribution, which is currently known only in some special cases [FS 2012].

Galois types

Let A be an abelian surface defined over a number field k .

Let K be the minimal extension of k for which $\text{End}(A_K) = \text{End}(A_{\bar{\mathbb{Q}}})$.

The group $\text{Gal}(K/k)$ acts on the \mathbb{R} -algebra $\text{End}(A_K)_{\mathbb{R}} = \text{End}(A_K) \otimes_{\mathbb{Z}} \mathbb{R}$.

The *Galois type* of A is the isomorphism class of $[\text{Gal}(K/k), \text{End}(A_K)_{\mathbb{R}}]$.

An isomorphism $[G, E] \simeq [G', E']$ is an isomorphism $G \simeq G'$ of groups and an equivariant isomorphism $E \simeq E'$ of \mathbb{R} -algebras.

One may have $G \simeq G'$ and $E \simeq E'$ but $[G, E] \not\simeq [G', E']$.

Galois types and Sato-Tate groups

Theorem 2 [FKRS 2012]

Up to conjugacy, the Sato-Tate group G of an abelian surface A is uniquely determined by its Galois type, and vice versa.

We also have $G/G^0 \simeq \text{Gal}(K/k)$, and G^0 is uniquely determined by the isomorphism class of $\text{End}(A_K)_{\mathbb{R}}$, and vice versa:

$U(1)$	$M_2(\mathbb{C})$	$U(1) \times SU(2)$	$\mathbb{C} \times \mathbb{R}$
$SU(2)$	$M_2(\mathbb{R})$	$SU(2) \times SU(2)$	$\mathbb{R} \times \mathbb{R}$
$U(1) \times U(1)$	$\mathbb{C} \times \mathbb{C}$	$USp(4)$	\mathbb{R}

There are 52 distinct Galois types in genus 2.

The proof uses the *algebraic Sato-Tate group* of Banaszak and Kedlaya, which, in genus $g \leq 3$, uniquely determines ST_A .

Exhibiting Sato-Tate groups in genus 2

The 34 Sato-Tate groups that can arise over \mathbb{Q} can all be realized as the Sato-Tate group of the Jacobian of a hyperelliptic curve that we are able to exhibit explicitly, following an extensive computational search.

The remaining 18 groups all arise as subgroups of these 34. These we obtain by simply extending fields of definition.

Searching for curves

We surveyed the \bar{L} -polynomial distributions of genus 2 curves

$$y^2 = x^5 + c_4x^4 + c_3x^3 + c_2x^2 + c_1x + c_0,$$

$$y^2 = x^6 + c_5x^5 + c_4x^4 + c_3x^3 + c_2x^2 + c_1x + c_0,$$

with integer coefficients $|c_i| \leq 128$, over 2^{48} curves.

We specifically searched for cases not already addressed in [KS09].

Searching for curves

We surveyed the \bar{L} -polynomial distributions of genus 2 curves

$$y^2 = x^5 + c_4x^4 + c_3x^3 + c_2x^2 + c_1x + c_0,$$

$$y^2 = x^6 + c_5x^5 + c_4x^4 + c_3x^3 + c_2x^2 + c_1x + c_0,$$

with integer coefficients $|c_i| \leq 128$, over 2^{48} curves.

We specifically searched for cases not already addressed in [KS09].

We found over 10 million non-isogenous curves with exceptional distributions, including at least 3 apparent matches for all of our target Sato-Tate groups.

Representative examples were computed to high precision $N = 2^{30}$.

For each example, the field K was then determined, allowing the Galois type, and hence the Sato-Tate group, to be **provably** identified.

Computational methods

There are four standard ways to compute $L_p(T)$ for a genus 2 curve:

- 1 point counting: $O(p^2 \log^{1+\epsilon} p)$.
- 2 group computation: $O(p^{3/4} \log^{1+\epsilon} p)$.
- 3 p -adic methods: $O(p^{1/2} \log^{2+\epsilon} p)$.
- 4 CRT approach: $O(\log^{8+\epsilon} p)$.

For the feasible range of $p \leq N$, we found (2) to be the best [KS08]. We can accelerate the computation with partial use of (1) and (4).

The `smalljac` software package provides an open source implementation of this approach (soon to be available in Sage).

A very recent breakthrough

All of the methods above perform separate computations for each p .
But we want to compute $L_p(T)$ for all good $p \leq N$ using reductions of *the same curve* in each case.

Is there a way to take advantage of this?

A very recent breakthrough

All of the methods above perform separate computations for each p . But we want to compute $L_p(T)$ for all good $p \leq N$ using reductions of *the same curve* in each case.

Is there a way to take advantage of this?

Theorem (Harvey, 2012)

Let $y^2 = f(x)$ be a hyperelliptic curve of genus g with $\log \|f\| = O(\log N)$. One can compute $L_p(T)$ for all odd $p \leq N$ with $p \nmid \text{disc}(f)$ in time

$$O(g^{8+\epsilon} N \log^{3+\epsilon} N).$$

This yields an average time of $O(g^{8+\epsilon} \log^{4+\epsilon} N)$ per prime.

This is the first algorithm to achieve an average running time that is polynomial in both g and $\log p$.

Some preliminary implementation results

With suitable optimizations, this algorithm can be made quite practical.

In genus 2 we are already able to surpass the performance of `smalljac` for $N \geq 2^{22}$, and further improvements are under way.

When combined with group computations in genus 3, we expect to obtain a dramatic improvement over existing methods.

We are also looking at adapting the algorithm to handle certain families of non-hyperelliptic curves, including Picard curves.

[Harvey-S, work in progress]

Harvey's algorithm in genus 1

The Hasse invariant h_p of an elliptic curve $y^2 = f(x) = x^3 + ax + b$ over \mathbb{F}_p is the coefficient of x^{p-1} in the polynomial $f(x)^{(p-1)/2}$.

We have $h_p \equiv t_p \pmod{p}$, which uniquely determines t_p for $p > 13$.

Naïve approach: iteratively compute $f, f^2, f^3, \dots, f^{(N-1)/2}$ in $\mathbb{Z}[x]$ and reduce the x^{p-1} coefficient of $f(x)^{(p-1)/2} \pmod{p}$ for each prime $p \leq N$.

Harvey's algorithm in genus 1

The Hasse invariant h_p of an elliptic curve $y^2 = f(x) = x^3 + ax + b$ over \mathbb{F}_p is the coefficient of x^{p-1} in the polynomial $f(x)^{(p-1)/2}$.

We have $h_p \equiv t_p \pmod{p}$, which uniquely determines t_p for $p > 13$.

But the polynomials f^n are huge, each has $\Omega(n^2)$ bits. It would take $\Omega(N^3)$ time to compute $f, \dots, f^{(N-1)/2}$ in $\mathbb{Z}[x]$.

So this is a terrible idea...

Harvey's algorithm in genus 1

The Hasse invariant h_p of an elliptic curve $y^2 = f(x) = x^3 + ax + b$ over \mathbb{F}_p is the coefficient of x^{p-1} in the polynomial $f(x)^{(p-1)/2}$.

We have $h_p \equiv t_p \pmod{p}$, which uniquely determines t_p for $p > 13$.

But the polynomials f^n are huge, each has $\Omega(n^2)$ bits. It would take $\Omega(N^3)$ time to compute $f, \dots, f^{(N-1)/2}$ in $\mathbb{Z}[x]$.

So this is a terrible idea...

But we don't need all the coefficients of f^n , we only need one; and we only need to know its value modulo $p = 2n + 1$.

A better approach

Let $f(x) = x^3 + ax + b$, and let f_k^n denote the coefficient of x^k in $f(x)^n$. Using $f^n = ff^{n-1}$ and $(f^n)' = nf'f^{n-1}$, one obtains the relations

$$(n+2)f_{2n-2}^n = n \left(2af_{2n-3}^{n-1} + 3bf_{2n-2}^{n-1} \right),$$

$$(2n-1)f_{2n-1}^n = n \left(3f_{2n-4}^{n-1} + af_{2n-2}^{n-1} \right),$$

$$2(2n-1)bf_{2n}^n = (n+1)af_{2n-4}^{n-1} + 3(2n-1)bf_{2n-3}^{n-1} - (n-1)a^2f_{2n-2}^{n-1}.$$

These allow us to compute the vector $w_n = [f_{2n-2}^n, f_{2n-1}^n, f_{2n}^n]$ from the vector $w_{n-1} = [f_{2n-4}^{n-1}, f_{2n-3}^{n-1}, f_{2n-2}^{n-1}]$ via multiplication by a 3×3 matrix M_n with entries in \mathbb{Q} . We have

$$w_n = w_0 M_1 M_2 \cdots M_n.$$

For $n = (p-1)/2$, the Hasse invariant of the elliptic curve $y^2 = f(x)$ over \mathbb{F}_p is obtained by reducing the third entry f_n^{2n} of w_n modulo p .

Computing $t_p \bmod p$

To compute $t_p \bmod p$ for all odd primes $p \leq N$ it suffices to compute

$$\begin{aligned} & M_1 \bmod 3 \\ & M_1 M_2 \bmod 5 \\ & M_1 M_2 M_3 \bmod 7 \\ & M_1 M_2 M_3 M_4 \bmod 9 \\ & \vdots \\ & M_1 M_2 M_3 \cdots M_{(N-1)/2} \bmod N \end{aligned}$$

Doing this naïvely would take $O(N^{2+\epsilon})$ time.

But it can be done in $O(N^{1+\epsilon})$ time using a *remainder tree*.

Remainder trees

Given matrices M_1, M_2, \dots, M_N and moduli m_1, m_2, \dots, m_N , we wish to compute remainders R_1, R_2, \dots, R_N , where $R_n = \prod_{i=1}^{n-1} M_i \bmod m_n$.

Algorithm for $N = 2^k$:

- 1 Compute a binary *product tree* with leaf values M_1, \dots, M_N and internal nodes whose values are the product of their children, and do the same for the moduli m_1, \dots, m_N .
- 2 Working from the top down, compute each node's *remainder* as the product of its parent's remainder and its left sibling's value, reduced modulo the node's modulus.

Each node's remainder is the product of the values in the leaves to its left, reduced modulo the node's modulus.

The leaf remainders are precisely R_1, \dots, R_N .

Using FFT-based arithmetic, this algorithm runs in quasi-linear time.

Hyperelliptic curves of genus $g > 1$.

The general algorithm uses Monsky-Washnitzer cohomology (as in Kedlaya's algorithm), but for $g \leq 3$ it is enough to just compute the Hasse-Witt matrix. This is the $g \times g$ matrix $W = [w_{ij}]$ with entries

$$w_{ij} = f_{pi-j}^{(p-1)/2} \pmod{p}.$$

Hyperelliptic curves of genus $g > 1$.

The general algorithm uses Monsky-Washnitzer cohomology (as in Kedlaya's algorithm), but for $g \leq 3$ it is enough to just compute the Hasse-Witt matrix. This is the $g \times g$ matrix $W = [w_{ij}]$ with entries

$$w_{ij} = f_{pi-j}^{(p-1)/2} \pmod{p}.$$

The w_{ij} can each be computed using recurrence relations between the coefficients of f^n and those of f^{n-1} , as in genus 1.

The characteristic polynomial of W determines the $L_p(T) \pmod{p}$.

Using group computations in the Jacobian of the curve, one can determine $L_p(T)$ exactly. This takes $\tilde{O}(1)$ time in genus 2, and $\tilde{O}(p^{1/4})$ time in genus 3, which turns out to be negligible within the feasible range of computation.

Sato-Tate in genus 3

For $g = 3$ there are 14 possibilities for the connected part of ST_A . There are at least 400 groups that satisfy the Sato-Tate axioms.

In order to realize cases with large component groups, one needs abelian threefolds with many endomorphisms. An obvious place to start is with Jacobians of curves with large automorphism groups (and their twists). Some notable cases enumerated by Wolfart:

$$\begin{aligned}y^2 &= x^8 - x, & y^2 &= x^7 - x, & y^2 &= x^8 - 1 \\y^2 &= x^8 - 14x^4 + 1, & y^3 &= x^4 - x, & y^3 &= x^4 - 1 \\x^4 + y^4 &= 1, & x^3y + y^3z + z^3x &= 0.\end{aligned}$$

However, Jacobians may not be enough!
